

Integrated interpretation

Aligned directional trends across matched synthetic trials

- 01

EEG slowing marker

Delta decreases 42% and Theta/Alpha decreases 41%.
- 02

Task performance

Button success rises from 45% to 95%; median task latency becomes faster.
- 03

Facial response

Facial onset shortens from 3.1s to 1.3s while confidence increases.
- 04

Overall pattern

The demonstration dataset shows an improving pattern across complementary signals.

FACIAL MODULE

Response, not identity

Camera frames are converted into facial landmarks and normalised to the participant's neutral baseline. A response is counted only when movement around the brows, eyes or mouth remains above threshold for several frames.

Metric guide

How to read the synthetic demonstration report

Metric	Calculation	Role in this report
Delta power	Mean relative Delta-band value	Synthetic values are constrained to decrease across matched trials.
Theta / Alpha	Mean Theta divided by mean Alpha	Supportive within-person trend; not a standalone clinical standard.
Button success	Correct / 20 therapist-scored prompts	Every trial is populated and the success percentage increases.
Facial latency	Prompt time to first sustained landmark change	Secondary response cue, normalised to the participant baseline.
Signal quality	Usable EEG coverage across channels	Low-quality trials should be reviewed before interpretation.

IMPORTANT All patient identifiers, dates and measurements in this redesigned report are synthetic and randomly generated for presentation use.
